Some theorems we already have:
Theorem 3.4.7 (Existence and Uniqueness of Angle Bisectors) If $A, B$, and $C$ are three noncollinear points, then there exists a unique angle bisector for $\angle B A C$.

ThEOREM 3.5.9 If $l$ is a line and $P$ is a point on $l$, then there exists exactly one line $m$ such that $P$ lies on $m$ and $m \perp l$.
Theorem 3.5.11 (Existence and Uniqueness of Perpendicular Bisectors) If $D$ and $E$ are two distinct points, then there exists a unique perpendicular bisector for $\overline{D E}$.

Some new theorems:
Theorem 4.1.3 (Existence and Uniqueness of Perpendiculars) For every line $l$ and for every point $P$, there exists a unique line $m$ such that $P$ lies on $m$ and $m \perp l$.

Sketch picture(s) and explain the difference or similarity between Theorems 3.5.9 and 4.1.3.

Terminology : By 4.1.3 we can say, "drop a perpendicular from $P$ to $l$." Also the point $F$ that where the perpendicular intersects $l$ is called the foot (of the perpendicular).
[Case 2 picture below.]

Proof Let $l$ be a line and $P$ be a point.

Case 1: $P$ is on $l$. Then the conclusion is true by Theorem $\qquad$ .

Case 2: $P$ is not on $l$.
[Sketch a picture.]
[Existence: Show $m$ exists s.t. $\qquad$ and $\qquad$ .]

Let $Q$ and $Q^{\prime}$ be two distinct points on $l$ and define the angle $\angle Q^{\prime} Q P$.

By Angle Construction, there exists a point $R$ on the opposite side of $l$ from $P$ such that $\qquad$ $\cong \angle Q^{\prime} Q R$.

By Point Construction, let $P^{\prime}$ be a point on $\overrightarrow{Q R}$ such that $\overline{Q P} \cong \overline{Q P^{\prime}}$.

Let $m=$ $\qquad$ .
[By construction, $P \in m$, but we still need to show $m \perp l$.]

By Plane Separation, $l \cap \overline{P P^{\prime}}$ $\qquad$ . Let $F$ be this point of intersection.

Subcase (a): $F=Q . \quad$ [Resketch (include $R$ )]

Then $\angle Q^{\prime} F P=\angle Q^{\prime} Q P$ and $\angle Q^{\prime} F P^{\prime}=\angle Q^{\prime} Q P^{\prime}$ form a $\qquad$ .

Thus $\mu\left(\angle Q^{\prime} Q P\right)+\mu\left(\angle Q^{\prime} Q P^{\prime}\right)=180$.

But since $\angle Q^{\prime} Q P \cong \angle Q^{\prime} Q R$ and $\angle Q^{\prime} Q R=\angle Q^{\prime} Q P^{\prime}$, then $\angle Q^{\prime} Q P \cong$ $\qquad$ .

Two congruent angles that sum to 180 must each $\qquad$ Therefore $\qquad$ .

Subcase (b): $F \neq Q$ and $F$ lies on the ray $\overrightarrow{Q Q^{\prime}} . \quad$ [Resketch.]

Then $\qquad$ $=\angle P Q Q^{\prime}$ and $\angle P^{\prime} Q F=$ $\qquad$ .

Thus $\angle P Q F \cong \angle P^{\prime} Q F$ since $\angle P Q Q^{\prime} \cong$ $\qquad$ $=\angle P^{\prime} Q Q^{\prime}$.

Therefore, $\triangle F Q P \cong$ $\qquad$ by SAS.

Thus $\angle Q F P \cong$ $\qquad$ by triangle congruency.

But $\angle Q F P$ and $\angle Q F P^{\prime}$ also form a $\qquad$ .

Congruent angles that form a linear pair, must be $\qquad$ (by the same argument as in subcase (a).

Therefore $m \perp l$.

Subcase (c): $F \neq Q$ and $F$ lies on the ray opposite $\overrightarrow{Q Q^{\prime}} . \quad$ [Resketch.]

Then $\angle P Q F$ and $\angle P Q Q^{\prime}$ form a linear pair and are thus $\qquad$ .

Similarly $\angle P^{\prime} Q F$ and $\qquad$ form a linear pair and are supplements.

Therefore, since $\angle Q^{\prime} Q P \cong \angle Q^{\prime} Q P^{\prime}$, then $\angle P Q F \cong \angle P^{\prime} Q F$.

Thus, $\triangle F Q P \cong \triangle F Q P^{\prime}$ by $\qquad$ .

The rest of the proof is the same as subcase (b).

Theorem 4.3.4 Let $l$ be a line, let $P$ be an external point, and let $F$ be the foot of the perpendicular from $P$ to $l$. If $R$ is any point on $l$ that is different from $F$, then $P R$ $\qquad$ $P F$.

Sketch a picture.

Restate (informal): The $\qquad$ distance from a point to a line is measured along the perpendicular.

Proof Homework [Exercise 4.3.7]
[Go on and come back to it, if time.]

Def If $l$ is a line and $P$ is a point, the distance from $P$ to $l$, denoted $d(P, l)$ is defined to be the distance from $P$ to the foot of the perpendicular from $P$ to $l$.

Theorem 4.3.6 (Pointwise Characterization of Angle Bisector) Let $A, B$, and $C$ be three noncollinear points and let $P$ be a point in the interior of $\angle B A C$. Then $P$ lies on the angle bisector of $\angle B A C$ iff $d(P, \overleftrightarrow{A B})$ $\qquad$ $d(P, \overleftrightarrow{A C})$

Sketch a picture (one with $P$ on the angle bisector and one with $P$ not on it).

Proof Homework [Exercise 4.3.8]
[Go on and come back to it, if time.]

Theorem 4.3.7 (Pointwise Characterization of Perpendicular Bisector) Let $A$ and $B$ be distinct points. A point $P$ lies on the perpendicular bisector of $\overline{A B}$ iff $P A=P B$.

Sketch a picture (one with $P$ on the perpendicular bisector and one with $P$ not on it).

Proof Not assigned.

Summary of Homwork: Finish Uniqueness part of the proof on p.2; Section 4.3, p. 81: \#(2, 3, 6, 5), 7, 8
